

# BankTransferPayment.java - Code Structure & Links

## 1. CLASS DEFINITION

```
public class BankTransferPayment extends Payment
```

Explanation: The third subclass linked to the Payment interface.

## 2. CLASS VARIABLES (FIELDS)

```
private String bankName;  
private String accountNumber;  
private String routingCode;
```

Explanation: Private fields that hold routing information. This isolates bank details from the rest of the application.

## 3. CONSTRUCTOR

```
public BankTransferPayment(...)
```

Explanation: Calls super() to initialize the base data, then saves the banking fields.

## 4. METHODS & ALGORITHMS

```
@Override  
public boolean process(BiConsumer<String, String> log)
```

Explanation: The execution algorithm for a Bank Wire.

Algorithm Flow:

1. Validation: Verifies the account number is at least 6 characters and routing code is provided.
2. Settlement: Instead of instant auth, it simulates a clearing house interbank connection, allowing transfers up to \$1,000,000 before returning success or failure.
