

PayPalPayment.java - Code Structure & Links

1. CLASS DEFINITION

```
public class PayPalPayment extends Payment
```

Explanation: A sibling subclass. It links to Payment the same way CreditCardPayment does, proving that siblings can share the same interface while being totally different internally.

2. CLASS VARIABLES (FIELDS)

```
private String email;  
private String password;
```

Explanation: Specific Encapsulated State. PayPal does not use card numbers, it requires an email and password. These are kept private.

3. CONSTRUCTOR

```
public PayPalPayment(...)
```

Explanation: Calls super() to link the base data to the parent class, then saves the email and password.

4. METHODS & ALGORITHMS

```
@Override  
public boolean process(BiConsumer<String, String> log)
```

Explanation: The execution algorithm for PayPal.

Algorithm Flow:

1. Validation: Checks if the email contains an "@" symbol and the password is at least 4 characters.
2. Authorization: Simulates an OAuth balance check (declines if > \$250,000). Updates the inherited status variable accordingly.
