

BankTransferPayment.java - Deep Dive Explanation

1. OVERVIEW & LINKAGE

The third Concrete Subclass. Bank transfers require routing numbers and account numbers. It simulates an interbank settlement process instead of an instant card authorization.

2. DETAILED CODE BREAKDOWN

```
private String bankName;  
private String accountNumber;  
private String routingCode;
```

Specific Encapsulated State: These private fields define the data required for a wire transfer.

```
boolean validDetails = accountNumber.length() >= 6 && routingCode.length() > 0;
```

Algorithm Step 1 (Validation): Verifies that the account number is long enough and the routing code was provided. Note how each payment class handles its own distinct validation logic.

```
boolean settled = amount <= 1_000_000;
```

Algorithm Step 2 (Settlement): Instead of an instant network auth, it simulates clearing house / interbank communication to settle the transfer. Bank transfers are allowed up to \$1,000,000 in this simulation before failing.
